Functional Description

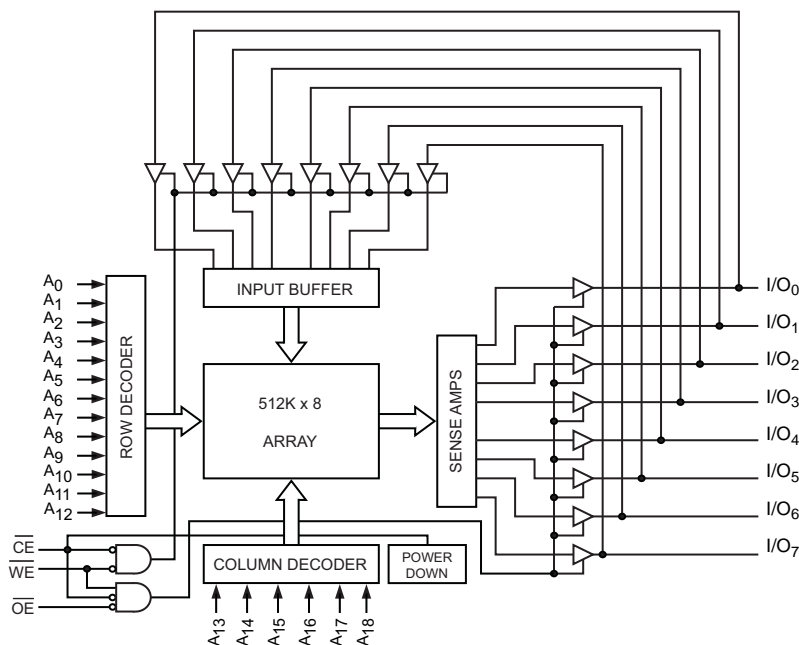

The CY62148E is a high performance CMOS static RAM organized as 512 K words by 8-bits. This device features advanced circuit design to provide ultra low active current. This is ideal for providing More Battery Life™ (MoBL[®]) in portable applications such as cellular telephones. The device also has an automatic power-down feature that significantly reduces power consumption when addresses are not toggling. Placing the device into standby mode reduces power consumption by more than 99% when deselected (\overline{CE} HIGH). The eight input and output pins (I/O₀ through I/O₇) are placed in a high impedance state when the device is deselected (\overline{CE} HIGH), Outputs are disabled (\overline{OE} HIGH), or during an active Write operation (\overline{CE} LOW and WE LOW)

To write to the device, take Chip Enable (\overline{CE}) and Write Enable (WE) inputs LOW. Data on the eight I/O pins (I/O₀ through I/O₇) is then written into the location specified on the address pins (A₀ through A₁₈).

To read from the device, take Chip Enable (\overline{CE}) and Output Enable (\overline{OE}) LOW while forcing Write Enable (WE) HIGH. Under these conditions, the contents of the memory location specified by the address pins appear on the I/O pins.

For best practice recommendations, refer to the Cypress application note [AN1064, SRAM System Guidelines](#).

Notes

- 14. Test conditions for all parameters other than tri-state parameters assume signal transition time of 3 ns or less, timing reference levels of 1.5 V, input pulse levels of 0 to 3 V, and output loading of the specified I_{OL}/I_{OH} as shown in the "AC Test Loads and Waveforms" on page 5.
- 15. SOIC package is available only in 55 ns speed bin.
- 16. At any temperature and voltage condition, t_{HZCE} is less than t_{LZCE}, t_{HZOE} is less than t_{LZOE}, and t_{HZWE} is less than t_{LZWE} for any device.
- 17. t_{HZOE}, t_{HZCE}, and t_{HZWE} transitions are measured when the outputs enter a high impedance state.
- 18. The internal write time of the memory is defined by the overlap of \overline{WE} , $\overline{CE} = V_{IL}$. All signals must be ACTIVE to initiate a write and any of these signals can terminate a write by going INACTIVE. The data input setup and hold timing should be referenced to the edge of the signal that terminates the write.

Notes

19. Device is continuously selected. \overline{OE} , $\overline{CE} = V_{IL}$.
20. WE is HIGH for read cycles.
21. Address valid before or similar to \overline{CE} transition LOW.
22. Data I/O is high impedance if $\overline{OE} = V_{IH}$.
23. If CE goes HIGH simultaneously with WE HIGH, the output remains in high impedance state.
24. During this period, the I/Os are in output state and input signals must not be applied.

- 26. If $\overline{\text{CE}}$ goes HIGH simultaneously with $\overline{\text{WE}}$ HIGH, the output remains in high impedance state.
- 27. During this period, the I/Os are in output state and input signals must not be applied.
- 28. Chip enable ($\overline{\text{CE}}$) must be HIGH at CMOS level to meet the $I_{\text{SB2}} / I_{\text{CCDR}}$ spec. Other inputs can be left floating.
