Functional Description ^[1]

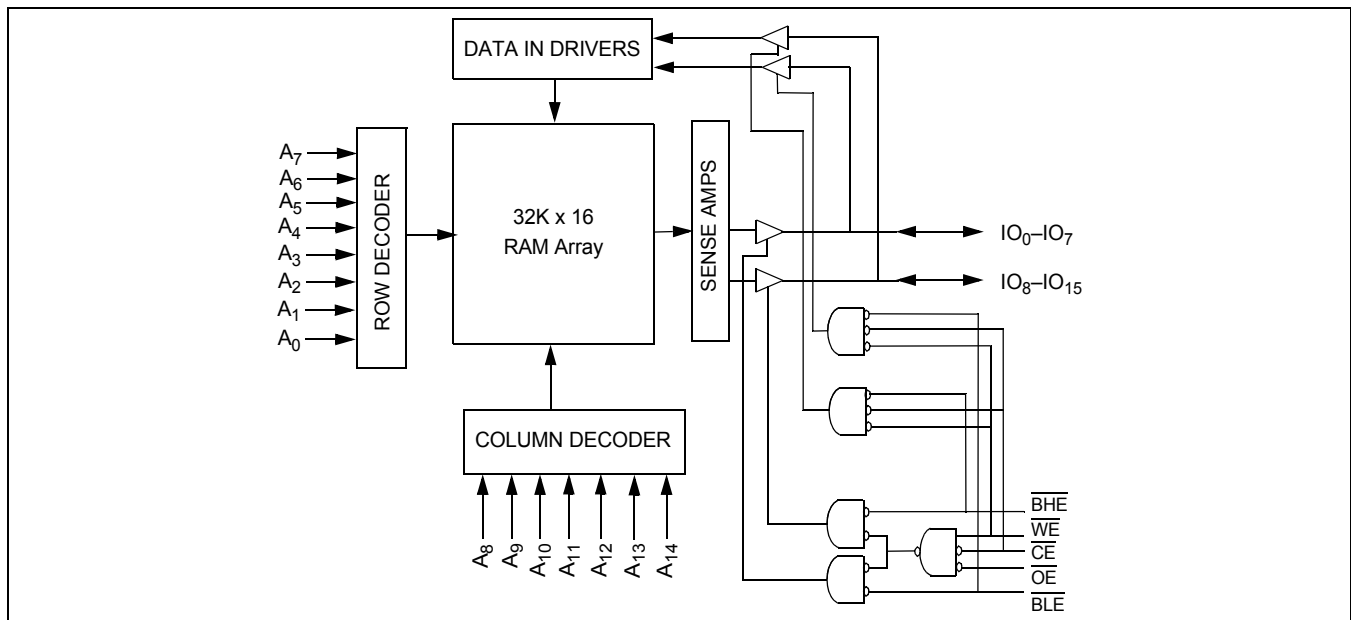

The CY7C1020D is a high-performance CMOS static RAM organized as 32,768 words by 16 bits. This device has an automatic power-down feature that significantly reduces power consumption when deselected. The input and output pins (IO_0 through IO_{15}) are placed in a high-impedance state when:

- Deselected (\overline{CE} HIGH)
- Outputs are disabled (\overline{OE} HIGH)
- \overline{BHE} and \overline{BLE} are disabled (\overline{BHE} , \overline{BLE} HIGH)
- When the write operation is active (\overline{CE} LOW, and \overline{WE} LOW)

Write to the device by taking Chip Enable (\overline{CE}) and Write Enable (\overline{WE}) inputs LOW. If Byte Low Enable (\overline{BLE}) is LOW, then data from IO pins (IO_0 through IO_7), is written into the location specified on the address pins (A_0 through A_{14}). If Byte High Enable (\overline{BHE}) is LOW, then data from IO pins (IO_8 through IO_{15}) is written into the location specified on the address pins (A_0 through A_{14}).

Reading from the device by taking Chip Enable (\overline{CE}) and Output Enable (\overline{OE}) LOW while forcing the Write Enable (\overline{WE}) HIGH. If Byte Low Enable (\overline{BLE}) is LOW, then data from the memory location specified by the address pins appears on IO_0 to IO_7 . If Byte High Enable (\overline{BHE}) is LOW, then data from memory appears on IO_8 to IO_{15} . See the "Truth Table" on page 8 for a complete description of read and write modes.

Notes

- Test conditions assume signal transition time of 3 ns or less, timing reference levels of 1.5V, input pulse levels of 0 to 3.0V, and output loading of the specified I_{OL}/I_{OH} and 30-pF load capacitance.
- t_{POWER} gives the minimum amount of time that the power supply should be at typical V_{CC} values until the first memory access can be performed.
- t_{HZOE} , t_{HZBE} , t_{HZCE} , and t_{HZWE} are specified with a load capacitance of 5 pF as in part (c) of "AC Test Loads and Waveforms [5]" on page 4. Transition is measured when the outputs enter a high impedance state.
- At any given temperature and voltage condition, t_{HZCE} is less than t_{LZCE} , t_{HZOE} is less than t_{LZOE} , and t_{HZWE} is less than t_{LZWE} for any given device.
- This parameter is guaranteed by design and is not tested.
- The internal write time of the memory is defined by the overlap of \overline{CE} LOW, \overline{WE} LOW and $\overline{BHE}/\overline{BLE}$ LOW. \overline{CE} , \overline{WE} and $\overline{BHE}/\overline{BLE}$ must be LOW to initiate a write and the transition of these signals can terminate the write. The input data set-up and hold timing should be referenced to the leading edge of the signal that terminates the write.
- The minimum write cycle time for Write Cycle No. 3 (\overline{WE} controlled, \overline{OE} LOW) is the sum of t_{HZWE} and t_{SD} .

Switching Waveforms

Read Cycle No.1 (Address Transition Controlled) [14, 15]

Read Cycle No.2 (\overline{OE} Controlled) [15, 16]

Notes

- 13. Full device operation requires linear V_{CC} ramp from V_{DR} to $V_{CC(min)} \geq 50 \mu s$ or stable at $V_{CC(min)} \geq 50 \mu s$.
- 14. Device is continuously selected. \overline{OE} , \overline{CE} , \overline{BHE} and/or $\overline{BLE} = V_{IL}$.
- 15. \overline{WE} is HIGH for read cycle.
- 16. Address valid prior to or coincident with \overline{CE} transition LOW.

Switching Waveforms(continued)

Write Cycle No. 1 ($\overline{\text{CE}}$ Controlled) [17, 18]

Write Cycle No. 2 ($\overline{\text{BLE}}$ or $\overline{\text{BHE}}$ Controlled) [17, 18]

Notes

17. Data IO is high impedance if $\overline{\text{OE}}$ or $\overline{\text{BHE}}$ and/or $\overline{\text{BLE}} = V_{\text{IH}}$.
18. If $\overline{\text{CE}}$ goes HIGH simultaneously with $\overline{\text{WE}}$ going HIGH, the output remains in a high-impedance state.

Write Cycle No. 3 (\overline{WE} Controlled, \overline{OE} LOW) [12, 18]
